Electrostatic Discharge (ESD) Suppression Design Guide. Electrostatic Discharge (ESD) is an electrical transient that poses a serious threat to electronic circuits. The most common cause is friction between two dissimilar materials, causing a buildup of electric charges on their surfaces. Typically, one of the surfaces is the human body, and it is not uncommon for this static charge to reach a potential as high as 15,000 volts.

Electrostatic Discharge (ESD) Protection Design Guide

Electrostatic discharge (ESD) protection design is needed for integrated circuits in CMOS technology. The choice for ESD protection devices in the CMOS technology includes diode, MOSFET, and silicon controlled rectifier (SCR). These ESD protection devices cause signal losses at high-frequency input/output (I/O) pads due to the parasitic capacitance.

ESD protection at circuit and assembly design: In order that electronics circuits can survive electrostatic discharges encounter in normal use, it is essential that protection is built in to the circuitry. This is normally important on any connections to the outside world. It is also necessary that sub-assemblies and boards have some measure of ESD protection so that when they are handled, the boards or sub-assemblies have some level of ESD protection.

ESD generated by triboelectric charging of the human body is often the most troublesome problem for portable computers. 1 Energy imparted during a discharge is usually in the form of a rapidly rising high voltage pulse with a slow exponential tail. ESD pulses can be modeled with the switching circuit shown in Figure 397.3.
