from the salivary glands and are carried in the bloodstream of the host to the liver where they invade hepatocytes to begin the exo-erythrocytic (EE) stage of development. Each parasite develops through a trophozoite form and then undergoes nuclear division (exo-erythrocytic schizogony) leading to the production of several thousand merozoites which are released and invade red blood cells.

The studies described in this paper cover attempts to infect chicken embryos by various routes with Plasmodium gallinaceum and efforts to discover exo-erythrocytic stages of development in the bone-marrow of general paralytics, in the spleen and other organs of persons who had died shortly after receiving malaria therapy or in the spleen of malaria patients during the latent period preceding...

Studies on the Exo-Erythrocytic Cycle of Malaria.

Studies made during the transitional stage infection of *P. gallinaceum* in chicks (i.e., the period of transition from tissue parasitism to parasitemia) have yielded the following results: 1. The relative frequency of exoerythrocytic stages expressed as number of parasites per square millimeter of section is fairly consistent for the two birds examined except for the kidney and spleen.

Information about exo-erythrocytic development of avian malaria parasites of the genus *Plasmodium* comes mainly from studies carried out by human malaria researchers who used these bird parasites, mainly of subgenera *Haemamoeba* and *Giovannolaia* as models for better understanding of human disease between the 1930s and 60s (reviews in [2–5, 7–9, 52, 54, 55]).

Exo-erythrocytic development of avian malaria and related ...

Exo-erythrocytic schizonts are characterized by never having malarial pigment (as they live in cells devoid of haemoglobin), by growing to a large size and forming numerous merozoites, up to 50 or 60 or even more. Exo-erythrocytic schizonts are not confined to leucocytes of the blood stream, but can also develop in fixed endothelial cells of organs such as the brain, lung, liver and spleen.

development of avian Plasmodium species and related haemosporidian parasites as a baseline for assisting academic and veterinary medicine researchers in morphological identification of these parasites using tissue stages, and to define future research priorities in this field of avian malariology.

Exo-erythrocytic development of avian malaria and related ...

A comparison with published data from other parasite stages confirmed stage-specific gene expression and revealed numerous genes that are expressed differentially in blood and exo-erythrocytic stages. One of the most exo-erythrocytic stage-specific genes was PBANKA_1003900, which has previously been annotated as a “gametocyte specific protein”. The promoter of this gene drove high GFP expression in exo-erythrocytic stages, confirming its expression profile seen by RNA-seq.

A light microscope study was made of the exoerythrocytic (EE) stages of Plasmodium knowlesi after intrahepatic inoculation of rhesus monkeys with sporozoites. Liver biopsy was first carried out 40 hours after inoculation and then at 8-hour intervals up to 136 hours, each monkey being biopsied twice. EE forms were seen first at 48 hours and development of the liver stages was completed in 112...
